ITT8060-2013-E2-SAMPLE

2

Question 1: True or False

Please circle T if the following statement is true and F if the statement is false.

- a. (T) (F) The value of List.fold (+) -1 [1;2;3;4] is 9. (2 points)
- b. (T) (F) Evaluating the expression ([1;2] :> System.Object) :?> intlist will succeed. (2 points)
- c. (T) (F) For abitrary n, accessing the last element of [|1 .. n|] will take linear time (as a function of n). (2 points)
- d. (T) (F) Evaluating the expression fst (lazy (1,2)) will fail because of type mismatch. (2 points)
- e. (T) (F) Taking the head of an empty list will fail at run time. (2 points)
- f. (T) (F) Evaluating the expression let x = printfn "hello"; 2 will print hello to the screen (2 points)
- g. (T) (F) The type of [(1,2,3)] is (int * int * int) list. (2 points)
- h. (T) (F) The type of Some (Some 42) is int option. (2 points)
- i. (T) (F) Evaluating the expression Option.bind Some None returns Some None. (2 points)
- j. (T) (F) The expression let rec t = seq {yield 1; yield! t} gen-erates an infinite sequence of increasing integers (2 points)
- k. (T) (F) The expression List.map (fun $n \rightarrow n + 2$) [1,3,5,7] returns [3,3,5,7] (2 points)

2

I. (T)(F) The type definition

defines leaf labelled trees (3 points)

ITT8060-2013-E2-SAMPLE

- -

List.fold left: ('a -> 'b -> 'a) -> 'a -> 'b list -> 'a

这个函数接受三个参数:

第一个参数是一个二元函数(接受两个参数的函数),用于将累积值和列表中的元素进行组合。

第二个参数是初始的累积值(accumulator),它是在折叠开始时的累积值。

第三个参数是要进行折叠操作的列表。

函数的行为是将列表中的元素从左到右依次传递给二元函数,同时更新累积值。这个过程会持续到列表中的所有元素都被处理完毕。最终,List.fold left返回的是最终的累积值。

b.试图将整数列表[1;2]先上转换(upcast)为System.Object,然后再尝试将其下转换(downcast)为int list类型。这个操作是不会成功的

([1;2]:> System. Object) 试图将整数列表 [1;2] 上转换为 System. Object 类型。在F#中,这个操作是允许的,因为每个类型在F#中都隐式地继承自 System. Object。

但是,:?>运算符用于下转换,即将一个基类型转换为派生类型。在这个例子中,你试图将 System. Object 下转换为 int list 类型。这个操作不会成功,因为 System. Object 类型不是 int list 类型的派生类型。因此,下转换会失败,表达式将导致运行时异常。

c 访问数组[|1..n|]的最后一个元素的时间是常数时间(constant time)

d 会成功求值,不会因为类型不匹配而导致失败。在这个表达式中,lazy 是一个延迟计算(lazy evaluation)的标记,它表示表达式将被延迟计算,直到它被实际需要的时候。

e 对于一个空列表(empty list),尝试获取其头部元素(head)会在运行时失败

f "hello" 会被打印到屏幕上。在F#中,分号;用于分隔多个表达式,这些表达式会按顺序执行。在这个表达式中,printfn "hello" 和 2 是两个连续的表达式,它们会被依次执行。所以,"hello" 会被打印到控制台上,并且 x 的值将会是 2。

h Some (Some 42) 的类型是 int option option, Some 42 创建了一个整数选项 (int option), 然后外部的 Some 封装了这个整数选项

i. 对于表达式 Option.bind Some None, 它的结果是 Some None。

在F#中,Option.bind 函数用于将一个选项(option)应用到一个函数,该函数的返回值也是一个选项。在这个例子中,Some 是一个包含某个值的选项,而 None 是一个表示空值的选项。当你将 Some 应用到 None 时,它会返回 None,而不会产生运行时错误。所以,Option.bind Some None 的结果是 Some None。

j它生成一个无限递增整数序列。这是因为在这个递归定义中,t是一个序列,其中包含了整数1,然后使用 yield!t表达式来递归地引入了t自身,形成了一个无限循环,生成无限递增的整数序列。

- k. 在F#中, 逗号用于构建元组
- 1. 定义了一个包含两种类型的树结构: Leaf 构造器用于表示带有整数标签的叶子节点,而 Node 构造器用于表示具有两个子树的内部节点。

Question 2: Trees 一种树形结构的数据表示,其中树的节点可以是字符串(string)或是两个子树的连接(concatenation)

Expressions made of only strings and concatenation can be represented using the following tree data structure:

```
type STree =
  | Val of string
  | Concat of STree * STree

a. Define an element of the STree type that corresponds to the informal representation ("a" @ "b") @ ("c" @ "d"). (3 points)
```

b. Given this function definition:

- (i) Evaluate the expressionf (Concat (Concat (Concat (Val "a", Val "b"), Val "c"), Val "d")).(3 points)
- (ii) Give the type of f. (3 points)
- (iii) Explain in words what the function f does. (3 points)
- c. Write a function that appends an exclamation mark "!" to every string in the tree. (5 points)
- d. Write a function flatten: STree -> string which concatenates all strings in the tree from left to right, e.g. flattening a tree corresponding to ("a" @ "b") @ ("c" @ "d") would result in a string "abcd". (5 points)
- e. What is the type of the function g defined below? (3 points)

```
let rec g f x =
  match x with
  | Val n -> Val (f n)
  | Concat (a,b) -> Concat (g f a,b)
```

e. ((string -> string) -> STree -> STree)

Concat / \ Val("ab") Val("cd")

a. Concat(Val("ab"), Val("cd"))

b(i) Concat (Concat (Val("ABC"), Val("D")))

b(ii) STree -> STree

c.

(iii) 函数 f接受一个 STree 类型的输入,然后根据输入的节点类型进行处理:

如果输入节点是 Val s,它将字符串 s 转换为大写,并返回一个新的 Val 节点,表示大写后的字符串。 如果输入节点是 Concat (a, b),它递归地对子节点 b 调用函数 f,然后用原始的节点 a 和处理过的子节点连接,返回一个新的 Concat 节点。 所以,函数 f 的作用是将输入的树中所有字符串节点转换为大写,并保持树的结构不变。

```
let rec addExclamationMark tree =
  match tree with
  | Val s -> Val (s + "!")
  | Concat (left, right) -> Concat (addExclamationMark left, addExclamationMark right)

d
let rec flatten tree =
  match tree with
  | Val s -> s
  | Concat (left, right) -> flatten left + flatten right
```

这个类型表示 g 是一个高阶函数,接受一个从字符串到字符串的函数 f,和一个 STree 类型的输入,并返回一个 STree 类型的输出。它可以将函数 f 应用到 STree 的每个字符串节点上。

Question 3: Lists

- a. Define a function first: 'a list -> 'a which returns the first element of a list. Define this function using pattern matching. If this list is empty return failwith "oops". (5 points)
- b. Given the following function g:

- (i) Evaluate the expression g (fun x \rightarrow x+1) [1..4]. (3 points)
- (ii) Give the type of g. (3 points)
- (iii) Explain in words what the function g does. (3 points)
- c. The function **zip** is supposed to create a list of pairs from the pair of lists given as arguments.

```
let zip (xs,ys) =
  match xs,ys with
    | []    , _ -> []
    | x :: xs', y :: ys' -> (x , y) :: zip (xs,ys)
```

- (i) Identify all the bugs. (6 points)
- d. Given a function min : int -> int -> int which returns the minimum of two arguments, each in the range -100 to 100, write a function minList : int list -> int that computes the minimum of a list of integers. (5 points)

```
a.
let first lst =
  match lst with
  [] -> failwith "oops"
  | hd :: _ -> hd
```

这个函数的作用是将列表 y 中的相邻两个元素进行处理,并将处理结果以交替的顺序连接在一起,其中一个元素经过函数 x 的处理。如果输入的列表元素少于两个,函数将返回原始列表。

(i) [1; 3; 3; 5]

(ii) ('a -> 'b) -> 'a list -> 'b list

(iii) 函数 g 的目的是将输入列表 y 中相邻的两个元素进行处理,其中第二个元素经过函数 x 的处理,然后将它们交替连接起来。如果输入列表元素少于两个,函数将返回原始列表。

模式匹配错误: Pattern Matching Bug:

在模式 (x::xs', y::ys') 中,试图将输入的列表 xs 和 ys 拆分为第一个元素和剩余部分。但是,这与函数的预期行为不符。应该直接匹配输入的列表 xs 和 ys。

修改: 将模式从 (x::xs', y::ys') 改为 (x::xs, y::ys)。

不完整的模式: Non-Exhaustive Patterns:

函数中有两个模式([],_和(x::xs, y::ys)),但没有处理一个列表为空而另一个不为空的情况。例如,如果 xs 是空的但 ys 不是,模式匹配将无法处理这种情况。

修改:添加一个模式来处理一个列表为空而另一个不为空的情况。例如,可以添加一个模式类似于([],[])->[],来处理两个列表都为空的情况。

Question 4: Option

There are several 3-valued logics. Kleene 3-valued logic is used in SQL database engines to deal with comparisons involving null values.

The behaviour of the 3-valued negation (NOT) can be given as follows:

A	NOT A
TRUE	FALSE
FALSE	TRUE
UNKNOWN	UNKNOWN

After noticing that the option type adds one value to the set of values of the type it wraps, we decide to use bool option type to implement such a logic, with TRUE implemented as Some true, FALSE as Some false and UNKNOWN as None.

- a. Write a function that converts from bool value to bool option. (2 points)
- b. Write a function that converts from bool option to bool (hint: use failwith "oops" in the case of None). (2 points)
- c. Implement the 3-valued negation function kleeneNeg: bool option -> bool option in F# by using pattern matching. (4 points)
- d. In Kleene logic the behaviour of the disjunction (OR) function can be given by the following table:

A OR B	A = TRUE	A = UNKOWN	A = FALSE
B = TRUE	TRUE	TRUE	TRUE
B = UNKNOWN	TRUE	UNKNOWN	UNKNOWN
B = FALSE	TRUE	UNKNOWN	FALSE

Implement the Kleene 3-valued logic disjuction as

kleeneOr : bool option -> bool option -> bool option. (5 points)

- e. Given that the implication in Kleene logic is defined as $A \to B = NOT(A)~OR~B,$ implement Kleene implication as
- kleeneImpl: bool option -> bool option -> bool option. (3 points)
- f. In Kleene 3-valued logic it is possible to assign integer values to FALSE = 0, UNKNOWN = 1 and TRUE = 2 and use the built in min function to compute the conjunction (AND). For example A AND B = MIN (A,B).

5

- (i) Write a function kleeneToInt : bool option -> int. (2 points)
- (ii) Write a function kleeneAnd: bool option -> bool option -> bool option that computes the conjunction of 2 arguments, and uses the built in min: int -> int -> int function. (3 points)

题目涉及到3值逻辑,特别是Kleene 3值逻辑,它在SQL数据库引擎中用于处理涉及空值(NULL values)的比较。在这个逻辑中,有三个可能的取值: TRUE(真),FALSE(假),和Unknown(未知)。为了实现这种逻辑,我们可以使用布尔选项类型(bool option type),其中TRUE被表示为Some true,FALSE被表示为Some false,而Unknown则被表示为None

```
let bool_to_option (b: bool): bool option =
 match b with
 | true -> Some true
 | false -> Some false
                                                    let kleeneNeg (bOpt: bool option): bool option =
                                                      match bOpt with
let option_to_bool (b_opt : bool option) : bool =
                                                      | Some true -> Some false
match b opt with
                                                      | Some false -> Some true
 | Some true -> true
                                                      | None -> None
 | Some false -> false
 | None -> failwith "oops"
   let kleeneOr (aOpt: bool option) (bOpt: bool option): bool option =
     match aOpt, bOpt with
     | Some true, _ | _, Some true -> Some true
     | Some false, Some false -> Some false
     | , -> None
   let kleeneImpl (aOpt: bool option) (bOpt: bool option): bool option =
      let notAOpt = kleeneNeg aOpt
      kleeneOr notAOpt bOpt
          let kleeneToInt (bOpt: bool option) : int =
             match bOpt with
             | Some true -> 2
             | Some false -> 0
```

ITT8060-2013-E2-SAMPLE

```
(2)
let kleeneAnd (aOpt: bool option) (bOpt: bool option) : bool option =
  let aInt = kleeneToInt aOpt
  let bInt = kleeneToInt bOpt
  let resultInt = min aInt bInt
  match resultInt with
  | 2 -> Some true
  | 1 -> None
  | 0 -> Some false
  |_ -> failwith "Invalid integer value"
```

| None -> 1

ITT8060-2013-E2-SAMPLE

6

g. Given the following function g:

let g x = Option.map not x

(The type of Option.map is ('a -> 'b) -> 'a option -> 'b option and the type of the Boolean not function is bool -> bool.)

- (i) Give the type of g. (2 points)
- (ii) Evaluate the expression g None. (2 points)

- (i) 函数 g 的类型可以从它的定义和所使用函数的类型来确定。
- Option.map 的类型是 ('a -> 'b) -> 'a option -> 'b option。not 函数的类型是 bool -> bool。在函数定义 g x = Option.map not x 中,x 的类型是 'a option。当 Option.map 被应用于 not 函数时,'a 的类型必须是 bool ,因为 not 函数接受一个 bool 类型的参数。
- (i) g: bool option -> bool option
- (ii) g None = None
- (ii) 对表达式 g None 的求值:

在F#中,Option.map 将一个函数应用于 Option 的内部值(如果是 Some 的话),否则返回 None。在这个情况下,g None 等同于 Option.map not None。

由于 None 中没有值(None 表示值的缺失),将 not 函数或任何函数应用于 None 都会得到 None。因此,g None 的求值结果是:

2

Please circle **A**, **B**, **C** or **D** according to which of them best matches the answer. In case there are multiple correct answers you should choose the best one. Only a single circle is considered to be the correct answer. In case you make a mistake, cross out the answer and write clearly next to the question what the answer is.

a. The expression List.filter (fun $(x,y) \rightarrow x>y$) [1,2;2,3;3,4;5,0] returns

A. [5,0]

- B. [1;2;3;5]
- C. [2;3;4;0]
- D. [1,2;2,3;3,4;5,0]

b. The value of 0 |> List.fold (>>) id [(+) 1; (*) 3; (-) 1] is

A. 2

- B. -11
- C. -2
- D. None of the above

(Given the type of the function (|>) is ('a -> ('a -> 'b) -> 'b) and the type of the function (>>) is (('a -> 'b) -> ('b -> 'c) -> 'a -> 'c))

c. Evaluating the expression (lazy (1,2)) will return

A. type error

- B. 2
- C. 1
- D. None of the above

d. Evaluating the expression Option.bind Some (None: bool option) returns, given the type of Option.bind is (('a -> 'b option) -> 'a option -> 'b option)

A. Some false

- B. false
- C. None
- D. Some Some false

e. The type of the expression printfn "nice day!"

A. string*int

- B. string
- C. unit
- D. int

f. A function of type 'a list -> 'int list -> 'a can be applied given the first argument is of type

A. int list

B. string list list C. all of the above D. none of the above

g. The type of the following function is

A. 'a list -> unit B. 'a list -> 'b listC. 'a list -> 'a listD. int

h. The type of the expression let f = fun x -> (fun y -> x+y) matches the type of the expression

A. let $g \times y = x * y$ B. let $g \times y = x + y$ C. Both of the above D. None of the above

- a 筛选出列表中所有符合条件 x>v 的元组
- b 将列表中的函数依次应用到累积器上,使用右复合运算符 (>>)
 - c 表示创建一个惰性(lazy)计算的值。在这种情况下,表达式 (1, 2)的计算会被延迟,直到需要使用这个值的时候才会被计算。
 - 一个懒惰计算的元组 (1, 2) Lazy<int * int>

d Option. bind 函数的类型签名为 ('a -> 'b option) -> 'a option -> 'b option。它的作用是将一个 'a option 的值与一个返回 'b option 的函数绑定在一起,如果输入的 'a option 是 Some x,则返回 f x,如果输入是 None,则结果也是 None。

e 输出字符串 "nice day!" 到控制台,但它不返回任何有意义的值,因此其类型是unit

f 如果有一个函数的类型为 'a list -> 'b list -> 'a, 那么该函数的第一个参数必须 是 'a list 类型的, 而第二个参数可以是任何类型的 'b list

g 根据函数的递归结构和模式匹配,该函数的类型应该是 'a list -> 'a list

```
创建了一个类型为 Async (unit) 的值。
 i. Evaluation of the following code will result in
                                                  这段代码定义了一个异步工作流 sleepWorkflow, 执行时, 它会打印 "starting", 暂停1000毫秒(1秒钟), 然后打印 "
   let sleepWorkflow = async {
                                                  finished"。但是,仅仅评估所示代码不会执行异步工作流。它仅定义了它并将其赋值给 sleepWorkflow。要执行工作流,
       printfn "starting"
       do! Async.Sleep 2000
                                                  你需要使用 Async. RunSynchronously、Async. Start 或其他运行异步工作流的函数。
       printfn "finished"
    A. A value of type
                        B. "starting" and
                                           C. A delay of 2000 ms; D. None of the above.
       Async<unit> being
                           "finishing" being printed;
       created;
 j. The function f defined below
   let rec f x =
       seq{
          yield x
          yield! f (x)
      }
     A. has type
                                                              D. None of the above.
                        B. has type
                                           C. has type
        'a -> 'b list.
                          int -> int list.
                                              'a -> seq<'a>.
 k. Given that the type of List.reduce is (('a -> 'a -> 'a) -> 'a list -> 'a),
   the expression List.reduce (*) [1] will evaluate to
                        B. [1]
                                                              D. none of the above.
    A. 1
                                           C. runtime error;
l. Given that the type of List.collect is (('a -> 'b list) -> 'a list -> 'b list), the expression
  List.collect (fun x -> [x + x]) [2; 3; 5] will evaluate to
    A. [[4];[9];[25]] B. [30]
                                          C. [4; 9; 25]
                                                             D. None of the above.
m. Given the declaration
  let rec g x y =
      match y with
      | [] -> 1
      | h :: t -> x h + g x t
    A. The type of g is B. g is tail recursive C. All of the above
                                                             D. None of the above
```

代码定义了一个名为 f 的递归函数,其功能是生成一个无限序列。这个函 数接受一个参数 x, 然后生成一个序列, 这个序列的第一个元素是 x, 后面跟 着通过递归调用 f 并传入相同的参数 x 所生成的序列的所有元素。

换句话说,这个函数将创建一个包含无限个 x 的序列。

k List. reduce 函数在 F# 中用于将列表中的元素通过某个函数进行累积运算, 最终得到 一个单一的结果

let sum = List. reduce (fun acc x \rightarrow acc + x) [1; 2; 3; 4; 5] printfn "The sum is: %d" sum

当列表中只有一个元素时,F# 不会抛出运行时错误,而是直接返回那个单一元素。

1. Apply the function to 2: 2 + 2 = 4, result: [4] Apply the function to 3: 3 + 3 = 6, result: [6] Apply the function to 5: 5 + 5 = 10, result: [10] Concatenate the results: [4: 6: 10] So, the expression will evaluate to [4: 6: 10].

List.collect 函数在 F# 中的作用是将一个函数应用于列表中的每个元素,并且收集(concatenate) 所有结果到一个列表中。其类型签名为('a -> 'b list) -> 'a list -> 'b list

(int -> int) -> int

list -> int

ITT8060-SAMPLE-EXAM-2019

Question 2: Partial functions

A function of type 'a -> 'b option can be thought of as a function of type 'a -> 'b that happens to be partial. This means that there may be values of type 'a where this function is undefined (we cannot produce a value of type 'b). The type 'a -> 'b option precisely says that given an 'a this function may produce a value of type 'b (failure to produce an output is represented by None).

There are library functions map and bind for Option with the given types:

```
Option.map : ('a -> 'b) -> 'a option -> 'b option
```

```
Option.bind : ('a -> 'b option) -> 'a option -> 'b option
```

Option.map can be used to apply an ordinary function ('a -> 'b) to an optional value to get an optional result.

Option.bind can be used to apply a partial function ('a \rightarrow 'b option) to an optional value to get an optional result.

a. Implement a function apply that allows to apply a partial function to an optional value to get an optional result:

```
apply: ('a -> 'b) option -> 'a option -> 'b option

For example, the result of apply (Some id) (Some 3) must be Some 3.

(5 points)
```

- (i) Evaluate apply (Some ((+) 1)) None (2 points)
- (ii) Evaluate apply (Some List.head) Some [3;2;1] (2 points)
- b. Implement the function

```
sequence : 'a option list \rightarrow 'a list option
```

so that given a list xs of optional values it evaluates to

- Some xs' when all of the optional values in xs were Some and xs' is a list of the values inside
- None when there was at least one None in xs.

```
Evaluating sequence [Some 1; Some 2] should evaluate to Some [1; 2]. Evaluating sequence [Some 1; None; Some 2] should evaluate to None. (7 points)
```

c. Implement the function

```
sequence' : 'a option list -> 'a list option
```

that behaves according to the specification of **sequence** but is implemented tail recursively. (7 points)

d. Give the type of the value that results evaluating the expression:

```
[Some [1;2;3]; Some [3;4]; None] |> sequence (2 points)
```

ITT8060-SAMPLE-EXAM-2019 4

部分函数 (partial functions) 的概念,其中函数的类型为'a -> 'b option,表示这是一个从类型'a到'b的函数,但它可能是不完全定义的,即在某些输入值'a上,该函数可能没有定义 (无法产生类型为'b的输出)。这种情况下,函数的返回值是'b option类型,其中None表示没有输出值,而Some x表示有输出值x。

Question 3: Expression trees

Given the following type definitions:

And the definition of the function lookup: v:VName -> vs:Assignment -> bool that looks up a bool value corresponding to the particular variable name VName:

a. Define the function interpret: e:Expr -> vs:Assignment -> bool that will determine if an expression e evaluates to true or false given the assingments to the variables in vs. Neg represents negation (not), And represents conjunction (&&) and Or represents disjunction (|||).

For example,

```
interpret (And (Or (Var "X1", Var "X2"), Neg (Var "X2"))) ["X1", true; "X2", false should evaluate to true.

(5 points)
```

b. Define a function

```
variables : e:Expr -> VName list
```

that returns all distinct names of the Boolean variables used in the expression. The results should contain distinct values, i.e. each name at most once.

```
Hint: consider using List.sort: ('a list -> 'a list) when 'a : comparison and/or List.groupBy: (('a -> 'b) -> 'a list -> ('b * 'a list) list) when 'b : equality library functions
```

For example, variables (And (Or (Var "X1", Var "X2"), Neg (Var "X2"))) should evaluate to ["X1"; "X2"].

(7 points)

c. Consider the following type of arithmetic expressions:

```
type Expr =
   | Const of int
   | Sum of Expr * Expr
   | Diff of Expr * Expr
   | Prod of Expr * Expr
```

A value Const n represents a primitive expression that denotes the number n, while values Sum e1 e2 Diff e1 e2, and Prod e1 e2, represent sums, differences, products, respectively.

Write a function eval : Expr -> int that evaluates the given expression.

(3 points)

d. Write a function commute: Expr -> Expr that swaps the arguments of all sums and products in the given expression (which should not change the result of the expression).

```
(4 points)
```

e. Polish notation is a notation for expressions where the operators come before their arguments and no parentheses are used. For example, the expressions 3 + 5, 3 + (4 * 5), and (3 + 4) * 5 are written + 3 5, + 3 * 4 5, and * + 3 4 5, respectively, when using Polish notation.

Write a function pn: Expr -> string that turns the given expression into its representation in Polish notation.

EXAM PAPER: AUTUMN 2021/22

Advanced Programming

ITT8060

Time allowed TWO Hours

Answer ALL FOUR questions

No calculators, mobile phones or other electronic devices capable of storing or retrieving text may be used.

A print text book (Real World Functional Programming, Functional Programming Using F#, or Expert F#) is allowed.

DO NOT open the examination paper until instructed to do so

Name:	
Student ID:	
Marks (to be filled by teaching staff):	

Question 1: Multiple choice

Please circle **A**, **B**, **C** or **D** according to which of them best matches the answer. In case there are multiple correct answers you should choose the best one. Only a single circle is considered to be the correct answer. In case you make a mistake, cross out the wrong answer and write clearly next to the question what the answer is.

a. Evaluating the expression List.filter (fun n \rightarrow n % 3 = 0) [3;9;1;8;4] returns c) [] a) [3;9] b) [3;9;1;8;4] d) Type error b. The value of List.fold (>>) id [(-) 3; (*) 2] 1 is b) -6 a) 4 c) Type error d) None of the above (Given the type of the function (>>) is (('a \rightarrow 'b) \rightarrow ('b \rightarrow 'c) \rightarrow 'a \rightarrow 'c) and the type of function id is 'a -> 'a) c. The type of (lazy (1,2)). Force () | is a) Lazy<int*int> b) int*int c) Lazy<int>*int d) Lazy<int>*Lazy<int> d. Evaluating the expression Option.bind Some (Some (None: bool option)) returns, given the type of Option.bind is (('a -> 'b option) -> 'a option -> 'b option) a) None b) false c) Some None d) Some Some None e. Evaluating the expression let rec s = seq {yield 3; yield! Seq.map (fun n -> n) s} produces a) An infinite sequence b) A sequence of 2 ints c) A list d) An error f. The type of the following function is let rec c b = match b with -> [] | d :: e -> e :: (c (List.map id e)) a) 'a list -> unit b) 'a list -> c) 'a list -> d) 'a list -> 'b list 'a list list 'a list g. The expression ["a",1;"b",3] |> List.map (id >> fst) will evaluate to

2

c) ["a",1;"b",3]

d) ["a";"b"]

b) [1;3]

ITT8060-2021-E3

a) 3

List.fold: ('State -> 'T -> 'State) -> 'State -> 'T list -> 'State

1. `List. fold` 是一个函数,它接受一个二元函数、一个初始累积器值和一个列表,然后使用该二元函数将列表中的每个元素与累积器值组合起来。

- 2. $`(\gt\gt)`$ 是一个函数组合运算符,它将两个函数组合成一个新的函数。例如, $`(f\gt\gt)$ g) x` 等同于 `g(f(x))`。
- 3. `id` 是一个恒等函数,它返回其参数不变。例如, `id x` 返回 `x`。
- 4. ` [(-) 3; (*) 2]` 是一个函数列表。列表中的第一个函数 ` (-) 3 ` 是一个将其参数减去3的函数,第二个函数 ` (*) 2 ` 是一个将其参数乘以2的函数。
- 5. `1` 是`List. fold`的初始累积器值。

现在, 让我们看看这个代码是如何工作的:

- 1. `List.fold` 从初始累积器值 `id` 开始。
- 2. 对于列表中的每个函数,它使用`(>>)`将累积器与该函数组合起来。这意味着每个新函数都会在前一个函数的结果上应用。

Question 2: Lists

a. Consider the following functions.

```
let foo x = printf "f"; 2 * x
let bar x = printf "b"; [x; x]
```

(i) What is the value that the following expression evaluates to? (2 points)

[1..5] |> List.map foo |> List.take 3 |> List.collect bar

- (ii) What is the string that is printed to the console by evaluating the above expression? (2 points)
- (iii) What is the value that the following expression evaluates to? (2 points)

```
[1..5] |> List.filter (fun i -> i % 2 = 0) |> List.map (bar << foo)
```

- (iv) What is the string that is printed to the console by evaluating the above expression? (2 points)
- b. (i) Define the function generate: int -> 'a -> 'a -> 'a -> 'a -> 'a) -> 'a list so that generate n a b f generates a list of values a₀,..., a_{n-1} where a₀ = a, a₁ = b and a_{k+2} = f a_k a_{k+1}. You may assume that the parameter n: int is non-negative.
 Example: generate 8 0 1 (+) should give the first 8 Fibonacci numbers: [0;1;1;2;3;5;8;13].
 Use explicit recursion (i.e., do not use any higher-order functions from the List module) and
 - (ii) Explain what it is that makes your solution not tail-recursive. (1 point)

(5 points)

c. Define the function applyEvens: ('a -> 'a) -> 'a list -> 'a list that applies the given function to elements at even positions in the list and leaves the other elements the same.

Define it using a fold operation over the input list. Pick an accumulator (type) that allows to keep track of whether you are at an even position or not. The first element in a list is at position 0.

```
Example: applyEvens ((*) 2) [1..5] must evaluate to [2;2;6;4;10]. (5 points)
```

d. Consider the following definitions.

make sure that your solution is *not* tail-recursive.

(i) What is the type of h? (3 points)

(ii) What is the result of evaluating: h [1;2;3;4]? (3 points)

Here are the types of some functions that may be relevant.

```
List.collect : ('a -> 'b list) -> 'a list -> 'b list
List.filter : ('a -> bool) -> 'a list -> 'a list
List.fold : ('b -> 'a -> 'b) -> 'b -> 'a list -> 'b
List.foldBack : ('a -> 'b -> 'b) -> 'a list -> 'b
List.map : ('a -> 'b) -> 'a list -> 'b list
List.replicate : int -> 'a -> 'a list
List.take : int -> 'a list -> 'a list
(<<) : ('b -> 'c) -> ('a -> 'b) -> 'a -> 'c
```

Question 3: Bags

We consider a bag to be a data structure which allows to associate keys with values together with their counts (how many times the key and value are associated). A key cannot be associated with two different values but it can be associated with the same value multiple times. Such a bag can be represented by a list of key-value-count triples. If the list contains a triple (k, v, c), then the key k and value v are associated v times. For example, (1, a, b, d) denotes a bag where the value v is associated to the key v and there is one instance of it in the data structure and the value v is associated to the key v and there are four instances of it in the data structure. In a v valid representation there should be no two triples with the same key.

a. Consider the following function definition:

(i) Evaluate the following expression:

```
[(1, 2, 1); (2, 4, 3); (3, 1, 2)] |> f 3 (3 points)
```

- (ii) Give the type of f. (3 points)
- (iii) Evaluate [] |> f "5". (3 points)
- b. Write a function

```
insert : 'a -> 'b -> ('a * 'b * int) list -> ('a * 'b * int) list
```

that inserts the given key and associated value into the given bag. That is to say that the result (bag) must associate the given value with the given key. If the key is already present in the bag and the values match, then the appropriate count should be incremented. In any other case the result (bag) should associate the given key and value exactly once. If the input bag is valid, then the result bag should also be valid. (5 points)

c. Given a function repeat that will apply the function f with initial argument x on its result c times (where c is positive),

```
let rec repeat c f x =
  match c with
  | 0 -> x
  | n -> repeat (n-1) f (f x)
```

write an expression that will apply insert with arguments where key is 2 and value is "b" on an initially empty list 4 times using repeat. (2 points)

d. Write a function

```
union : ('a * 'b * int) list -> ('a * 'b * int) list -> ('a * 'b * int) list
```

that forms the union of two bags. The union contains all the key-value-count triples of both bags where coinciding keys and values will have summed counts. If some key is contained by both bags, but the values do not match, only the corresponding value and count in the first bag will be preserved in the union. Use List.fold to invoke the combination of repeat and insert functions repeatedly, starting from the second argument. (4 points)

e. Consider the following code:

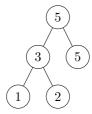

The function check is supposed to check if a given list of triples is a valid representation of a bag, that is, it does not contain any key more than once. The code contains bugs. Identify all of them. (5 points)

Question 4: Trees

Here is a definition of node-labelled binary trees that is parametric in the type of labels. A tree can either be *empty* or it can be a *branch* (node) holding a value of type 'a and two subtrees: left and right.

```
type 'a tree = Empty
| Branch of 'a tree * 'a * 'a tree
```

a. Define a value of type int tree that represents the following tree (empty subtrees are omitted from the picture): (2 points)

- b. Define the function truncate: int -> 'a tree -> 'a tree that truncates the given tree at the given depth (int). We consider the root node to be at depth 0. By truncating at depth n we mean that all the subtrees whose root is at depth n in the given tree must be replaced by the empty tree. You may assume that depth is non-negative. (4 points)
- c. Define the function map: ('a -> 'b) -> 'a tree -> 'b tree that transforms the given tree by applying the given function to every label in the tree. The result tree should have exactly the same shape as the input tree and a label in the result tree should be obtained by applying the given function to the label at the corresponding position in the input tree. (4 points)
- d. A heap is a tree-based data structure which is essentially an almost complete tree that satisfies the heap property: in a max heap, for any given node c, if p is the parent node of c, then the label of p is greater than or equal to the label of c. Define the function lessOrEq: int tree -> int option -> bool that checks whether the given tree satisfies the max heap property. If the second argument is Some n, then the parent node of the tree (first argument) was labelled by n. If the second argument is None, then the tree did not have a parent node.

 (4 points)
- e. Define the function heapLike: int tree -> bool that evaluates to true precisely when the given tree satisfies the max heap property. Use lessOrEq in your solution. (1 point)
- f. A binary search tree (BST) is a binary tree whose (internal) nodes store a label greater than all the labels in the node's left subtree and less than those in its right subtree. We consider trees ('k * 'v) tree where the labels are pairs of a key and a value to represent dictionaries. Labels of type 'k * 'v are ordered according to the first component (the keys). Define the function insert: 'k -> 'v -> ('k * 'v) tree -> ('k * 'v) tree that inserts the given key and value to the correct position in the tree. Assume that the given tree is a BST and ensure that the result is then also a BST. If there is already a label with the given key in the tree, then the value should be updated. Otherwise a new label must be inserted. (5 points)
- g. Define the function split: 'a tree -> ('a list * 'a * 'a list) option that decomposes the given tree into three components. The function should evaluate to Some (ls, a, rs) if the given tree contains at least one label. Otherwise it should evaluate to None. In the first case, a should be the label of the root of the tree, ls should hold the labels from the nodes that are the left child of their parent, and rs should hold the labels from the nodes that are the right child of their parent. The order of elements in the result (in ls and rs) does not matter but the number of elements (of type 'a) in the tree and in the result should be the same (i.e., preserve duplicates).
